

# Wireless Coexistence in the 2.4 GHz Band

## 1. Introduction

The tests described in this document aim to determine the effects of coexistence in the 2.4 GHz radio band of the main wireless technologies that are using these bands: IEEE Std. 802.15.4, IEEE Std. 802.11 (Wi-Fi), and Bluetooth Smart.

The main purpose of the tests is to determine the performance of an IEEE Std. 802.15.4 radio when operating with Wi-Fi static and dynamic interference, BLE interference, or combined Wi-Fi and BLE interference. The IEEE Std. 802.15.4 radio used for testing is the Freescale KW24 wireless MCU and the Bluetooth Smart radio used for testing is the Freescale KW40Z wireless MCU.

The test results determine the best and worst case scenarios when different wireless technologies coexist.

These tests will enable you to:

- setup different wireless networks that may coexist
- understand the effects of mutual interference
- learn which channels are recommended for use and which are not
- ensure proper distances between and correct placement of wireless networks.

IEEE Std. 802.15.4 defines 16 channels. The first channel is channel 11 (with a central frequency of 2405 MHz) and the last channel is 26 (with a central frequency of 2480 MHz). Each channel has a 2 MHz bandwidth and a 5 MHz channel spacing.

IEEE Std. 802.11 defines a total of 14 channels however in contrast with IEEE 802.15.4, the channel usage depends on the regulatory domain. IEEE Std. 802.11b recommends the use of non-overlapping channels 1, 6, and 11 for North America and channels 1, 7, and 13 for Europe. Also, for North America channels 13 and 14 are not used. See [Figure 1](#).

IEEE Std. 802.15.4 is designed to ensure a reliable co-existence with other 2.4 GHz wireless technologies and provides mechanisms that improve or enhance this co-existence. These mechanisms can be found in Annex E of the IEEE 802.15.4 specification.

The following figure demonstrates that for both North America and Europe you can choose up to four 802.15.4 channels that are not overlapping the Wi-Fi channels.

**Figure 1. IEEE 802.15.4 channel vs. non-overlapping IEEE 802.11b channels (US, Europe)**

Coexistence among wireless technologies is dependent on three main factors:

- Frequency
- Time
- Space

If one (at least) of these three factors can be controlled, then coexistence can be achieved by:

- Frequency separation between networks' operating channels
- Low occupancy of the channel
- Setting convenient distances between networks/nodes.

However in real world deployment none of these three main factors can be fully controlled and therefore the interference will always exist. The objective is to achieve an acceptable level of performance of services delivered by the coexisting wireless technologies.

IEEE Std. 802.11n adds new features such as MIMO, channel bonding, and frame aggregation to achieve higher throughput.

- MIMO uses multiple transmit and receive antennas to achieve higher throughputs. Spatial multiplexing and spatial diversity are the most commonly used techniques. Data rates, the modulation technique, and the number of streams are defined by IEEE Std. 802.11n by the mean of the MCS index.
- Channel bonding: IEEE Std. 802.11n specifies a new mode that uses a 40MHz channel. This channel is formed by two adjacent 20 MHz bands - therefore the PHY data rate can be increased by up to 2 times.
- Frame aggregation is also used to increase the throughput. Every frame transmitted by an IEEE 802.11n device has a significant amount of overhead (headers, frame fields, interspersing frames, ACK frames) and this overhead can consume at higher data rates more bandwidth than the payload frames. IEEE Std. 802.11n defines two frame aggregation types to deal with this: MSDU aggregation and MPDU aggregation. Each aggregation type groups several data frames into a single larger one. Since the management information has to be specified only once per data frame, a higher throughput is therefore achieved.

The modulation type for both IEEE 802.11n and 802.11ac is OFDM. IEEE 802.11b and IEEE 802.15.4 use modulation type DSSS. IEEE 802.11g uses modulation type OFDM or DSSS. Due to this IEEE 802.11n can work more effectively with an IEEE 802.15.4 network. If possible the frame aggregation (FA) level must be set to acceptable values. If the FA level is set too high, the Wi-Fi packets are longer and the time to transmit the Wi-Fi packets is increased leaving too little time for the 802.15.4 network to transmit its own packets (considering CCA enabled).

Figure 2. IEEE 802.11 n Power Spectral Density (OFDM modulation)

Figure 3. IEEE 802.15.4 Power Spectral Density (DSSS modulation)

## 2. Lab tests: IEEE 802.15.4 – IEEE 802.11n coexistence

### 2.1. Energy scan

An energy scan is performed on 802.15.4 radio channels when operating with 802.11 dynamic interference.

#### 2.1.1. Hardware components

For the Energy scan tests, the following items are used:

- Tescom TC-5916A shield box
- TP-Link wireless AP
- USB to ETH converter
- FRDM-K64F plus FRDM TWRPI shield with MCR20 radio transceiver
- TWR-KW24D512 tower card
- Manhattan USB hub
- Samsung Galaxy tablet (Android OS)
- Cables
- Power Supply for USB hub

All the items are placed inside the RF chamber during testing.

#### 2.1.2. Software components

The firmware running on the TWR-KW24D512 tower card and the K64F+MCR20 setup is dependent on the tests that are executed:

- SMAC Connectivity Test – energy scan test

The following PC software applications are used:

- Universal media server
- TeraTerm
- Octave
- Test Tool
- inSSIDer

On the Android tablet the following applications are used:

- Bubble uPNP
- Wi-Fi Analyzer
- Media Player

On the WiFi router the following is used:

- Openwrt firmware.

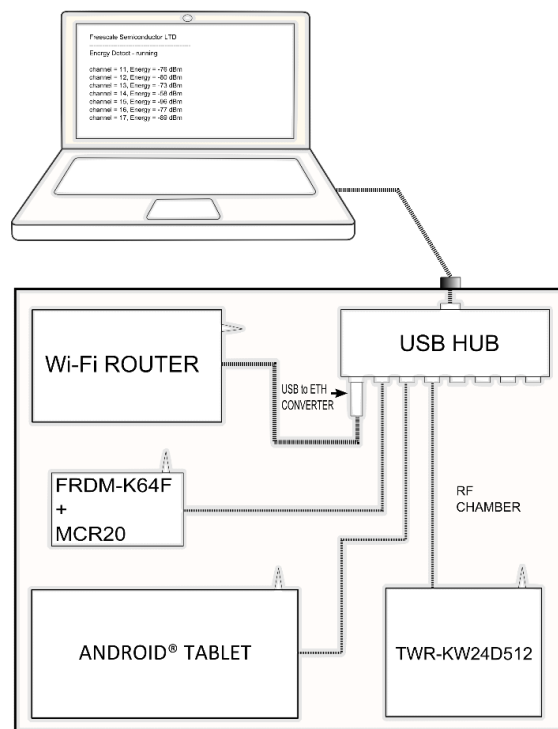

Figure 4. Energy detect hardware setup

### 2.1.3. System setup

The energy detect (energy scan) tests were performed within the RF chamber. Two 802.15.4 devices were used (TWR-KW24D512 tower card and FRDM-K64F as well as a MCR20 radio).

On the PC, the Universal Media Server software is running a DLNA server. The laptop is connected to the RF chamber via a USB cable. The cable is connected inside the chamber to a USB hub. A USB to ETH converter is connected to the USB hub; the ETH cable is connected to the Wi-Fi access point.

The Android OS tablet is running a DLNA player application (Bubble uPNP) and is generating dynamic traffic with the AP by playing a 1080p video. The two 802.15.4 devices are located at different positions relative to the Wi-Fi physical setup and both nodes sequentially measure the energy on all 802.15.4 channels. The 802.11n channels used are: channel 1, channel 6, and channel 11. The 802.11n transmission power auto-leveling algorithms are disabled and three transmission powers are used: 0 dBm, 12 dBm and 14 dBm.

### 2.1.4. Experimental results

The results are logged in files and then filtered and processed using octave scripts. The results are averaged in plots to ensure that they are observed efficiently.

### 2.1.5. Conclusions:

- The IEEE 802.11 energy is seen as additive white Gaussian noise by the IEEE 802.15.4 radios.
- The IEEE 802.15.4 radio sensitivity is altered about 20 dBm on the converging frequencies (overlapping channels).
- RSSI/LQI is a poor indicator of link quality in noisy environments.
- If CSMA-CA is enabled, then the CCA threshold must be set taking into consideration the interference level of the coexisting networks.

## 2.2. Packet error rate test

A packet error rate test is performed on 802.15.4 radio channels when operating with 802.11 dynamic interference

### 2.2.1. Hardware components:

For the packet error rate tests, the following items were used:

- Tescom TC-5916A Shield Box
- TP-Link wireless AP
- USB to ETH converter
- 2 x TWR-KW24D512 tower card
- Manhattan USB hub
- Samsung Galaxy tablet (Android OS)
- Samsung Galaxy S3 smartphone (Android OS)
- Cables
- Power Supply for USB hub

All items are placed inside the RF chamber during testing.

### 2.2.2. Software components:

For the two TWR-KW24D512 tower card the following firmware has been used:

- 802.15.4\_MAC2006\_KW24D512\_CoexistenceTool.srec

On the PC software side, the following applications have been used:

- Test Tool with Coexistence Tool
- Octave
- TeraTerm
- Microsoft Excel 2013
- inSSIDer
- jPerf

On the Android tablet the following applications are used:

- iPerf Server
- Wi-Fi Analyzer
- Terminal Emulator

On the Android smartphone the following applications are used:

- iPerf Client
- Wi-Fi Analyzer
- Terminal Emulator

On the Wi-Fi router the following is used:

- OpenWrt firmware.

The hardware setup can be seen in the following figure:

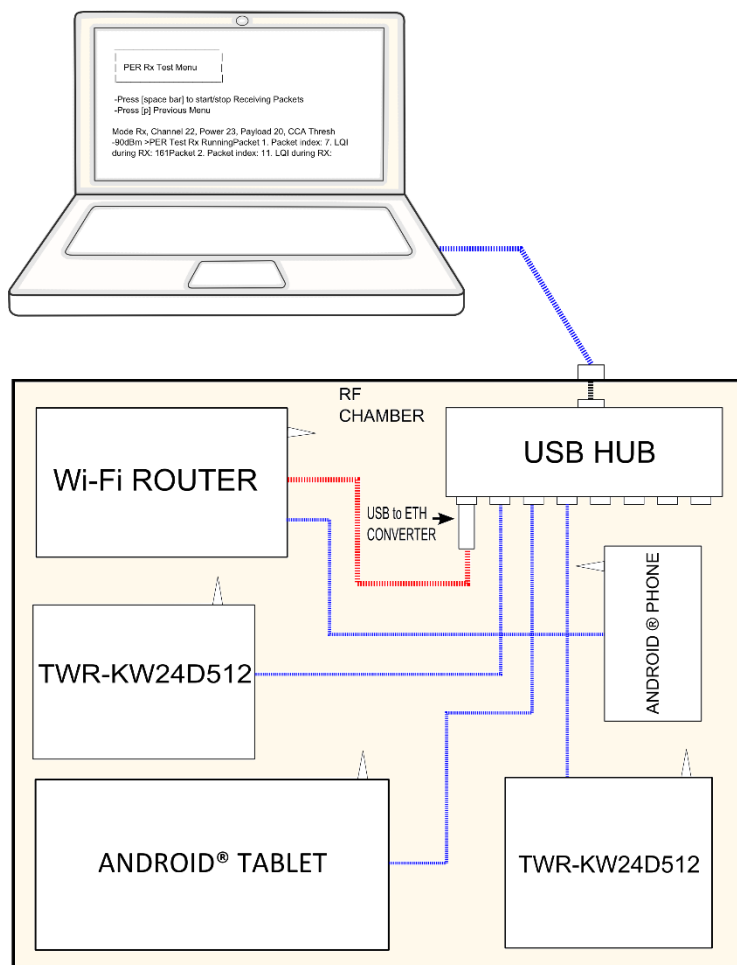

Figure 23. PER Tests HW setup

### 2.2.3. System setup

In [Figure 23](#) the red cable represents the ETH cable and the blue ones represent USB cables.

The following PER test was performed: PER test on overlapping channels, Wi-Fi channel 11 (2.462 GHz) and 802.15.4 channels 21 (2.455 GHz), 22(2.460 GHz), 23(2.465 GHz) and 24 (2.470 GHz) at constant Wi-Fi transmission power level but different throughputs, constant 802.15.4 transmission power and packet length, CCA enabled. A test with the same Wi-Fi configurations (same constant power and channel with the same throughput values) was done with a non-overlapping channel that is close to one of the overlapping channels (802.15.4 channel 20 (2.450 GHz)) because the energy detection tests showed that the Wi-Fi signal was detected as noise on other channels besides the overlapping ones.

The Wi-Fi router provided an USB port where the smart phone was connected and a network connection between them was established using USB tethering; the Android tablet was connected to the Wi-Fi

router over the air. In the Wi-Fi router the two networks (on Wi-Fi and USB) were bridged and a network connection between the smartphone and the tablet was established. A client-server connection was established between the two devices using iPerf Android App. The OpenWrt firmware on the Wi-Fi router offers more control of the Wi-Fi traffic (possibility to control the router's Wi-Fi transceiver output power and the Wi-Fi channel) so it is preferred that the Wi-Fi traffic comes from the router to the tablet.

Data is transferred in UDP datagrams at different throughputs (0.5, 1, 5, 10, 15, 20, 25, 30, 35, 40, and 45 Mbits/sec) from the iPerf client application on the smartphone through USB tethering to the router. The router forwards the UDP datagrams to the tablet via Wi-Fi at constant power and on a fixed channel (Wi-Fi channel 11 at 2.462 GHz).

With this setup, a stable and controlled level of interference was achieved for the IEEE 802.15.4 network.

On the IEEE 802.15.4 side we have two KW24-D512 TOWER boards running the 802.15.4\_MAC2006\_KW24D512\_CoexistenceTool.srec firmware which was downloaded from Test Tool.

The Coexistence Tool from the Test Tool software was used to configure and control the boards and to gather the test data.

The boards were configured to send 5000 packets from one to the other at a 5ms rate with MAC acknowledge request set to true, with 4 retry attempts, at nominal output power, with 100 B bytes payload and a fixed base channel for each test (there is one test for each of the following channels: 20, 21, 22, 23, and 24, forming a test suite). Each test suite was repeated for each Wi-Fi bandwidth value mentioned earlier in the document.

The Coexistence Tool provided PER values and a time graph showing when a packet was successfully sent or was lost. Based on this graph and the logs from iPerf it was possible to eliminate statistically incorrect data in order to have more accurate results (for example the graph mostly showed dropped packets and there was an interval with 0% PER, if the logs in iPerf showed that the Wi-Fi bandwidth fluctuated significantly that specific data was eliminated from the results and the PER was recalculated).

The data from Test Tool was exported to an Excel spreadsheet and then transferred to an Octave.m file, where it was processed and plotted.

The first set of test were run with the router's output power set to 14 dBm (25 mW) and the second set of tests were run with the router's output power set to 0dBm (1mW). The distance between boards was 20–25 cm. The distance between one of the boards and the router was 5 cm and the distance between the same board and the tablet was approximately 5 cm.

## 2.2.4. Experimental results

**Figure 24. PER results: test case 1**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 14 dBm (25 mW)
  - 802.15.4 channel: 20
  - 802.15.4 payload size: 100 B

**Figure 25. PER results: test case 2**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 14 dBm (25 mW)
  - 802.15.4 channel: 21
  - 802.15.4 payload size: 100 B

**Figure 26. PER result: test case 3**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 14 dBm (25 mW)
  - 802.15.4 channel: 22
  - 802.15.4 payload size: 100 B

**Figure 27. PER results: test case 4**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 14 dBm (25 mW)
  - 802.15.4 channel: 23
  - 802.15.4 payload size: 100 B

**Figure 28. PER results: test case 5**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 14 dBm (25 mW)
  - 802.15.4 channel: 24
  - 802.15.4 payload size: 100 B

**Figure 29. PER results: test case 6**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 0 dBm (1 mW)
  - 802.15.4 channel: 20
  - 802.15.4 payload size: 100 B

**Figure 30. PER results: test case 7**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 0 dBm (1 mW)
  - 802.15.4 channel: 21
  - 802.15.4 payload size: 100 B

**Figure 31. PER results: test case 8**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 0 dBm (1 mW)
  - 802.15.4 channel: 22
  - 802.15.4 payload size: 100 B

**Figure 32. PER results: test case 9**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 0 dBm (1 mW)
  - 802.15.4 channel: 23
  - 802.15.4 payload size: 100 B

**Figure 33. PER results: test case 10**

802.15.4 PER results. The following parameters were used:

- Wifi channel: 11 (2.462 GHz)
- Wifi Tx power: 0 dBm (1 mW)
  - 802.15.4 channel: 24
  - 802.15.4 payload size: 100 B

### 2.2.5. Conclusions:

- The IEEE 802.11 traffic is affecting not only the overlapping channels but also adjacent channels of the overlapping channels, as can be seen in [Figure 24](#) (for 802.15.4 channel 20 - 2.450 GHz and 802.11 channel 11 – 2.462 GHz), but the impact is weaker.
- For the adjacent channels of the overlapping channels significant PERs are obtained for throughputs higher than 35 Mbps (at 25 mW TX power).
- Even with ACK Request option set to true, with 4 packet retries, the packet error rates are high even at lower throughputs on overlapping channels if the Wi-Fi router is placed very close to the 802.15.4 nodes and the router has a high output power.
- All of the overlapping 802.15.4 channels (channels 21, 22, 23, and 24 in this test) with the 802.11 channel (channel 11 in this test) are affected similarly (relatively close PER values for every overlapping channel for each separate Wi-Fi throughput).
- By reducing the 802.11 router's output power by 25 times from 14 dBm (25 mW) to 0 dBm

(1 mW), the PER has been significantly reduced. It can be seen that for the overlapping channels, at throughputs equal or less than 15 Mbps, the PER is negligible and at about 20 Mbps the PER is very small. The neighboring adjacent channels are noticeably affected only when the throughput is over 30 Mbps.

### 3. Acronyms and abbreviations

Acronym / Term	Definition
BLE	Bluetooth Low Energy (Bluetooth Smart)
WLAN	Wireless Local Area Network
WPAN	Wireless Personal Area Network
